CERTIFICATE

This is to certify that the project entitled - "Groundnut Leaf Disease Detection for Low-Cost Field Devices" is being submitted by Y. DOMNIC VAMSHI (23261A6664), C. RAHUL (23261A6608), S. SREEMAYEE (23261A6651), in partial fulfillment of the requirements for the Complex Engineering Problem Task / Project (CM701PC / CM751PC) in COMPUTER SCIENCE AND ENGINEERING (DATA SCIENCE) is a record of bonafide work carried out by them under our guidance and supervision. The results of the investigations enclosed in this report have been verified and found satisfactory.

PROJECT GUIDE
Dr. M.Rudra Kumar
Professor, Dept. of ET

HEAD OF THE DEPARTMENT
Dr. M. Ramabai
Professor & Head, Department of ET

DECLARATION

This is to certify that the work reported in this project titled - "Groundnut Leaf Disease Detection for Low-Cost Field Devices" is a record of work done by us in the Department of Emerging Technologies, Mahatma Gandhi Institute of Technology, Hyderabad.

No part of the work is copied from books / journals / internet and wherever the portion is taken, the same has been duly referred to in the text. The report is based on the work done entirely by us and not copied from any other source.

Y. DOMNIC VAMSHI (23261A6664)
C. RAHUL (23261A6608)
S. SREEMAYEE (23261A6651)

ACKNOWLEDGEMENT

The satisfaction that accompanies the successful completion of any task would be incomplete without the mention of people who made it possible, because success is the abstract of hard work and perseverance, but steadfast of all is encouraging guidance. So, we acknowledge all those whose guidance and encouragement served as a beacon light and crowned our efforts with success.

We would like to express our sincere thanks to Prof. G. Chandra Mohan Reddy, Principal, MGIT, for providing the working facilities in college.

We wish to express our sincere thanks and gratitude to Dr. M. Ramabai, Professor and HoD, Department of Emerging Technologies, MGIT, for all the timely support and valuable suggestions during the period of the project.

We are extremely thankful and indebted to our internal guide and mentor Ms. E. Sathiya Lakshmi, Assistant Professor, Department of Emerging Technologies, for her constant guidance, encouragement and moral support throughout the project.

We also extend our sincere gratitude to the project coordinators, Department of Emerging Technologies, for their valuable support and coordination.

Finally, we would also like to thank all the faculty and staff of the Emerging Technologies Department who helped us directly or indirectly to complete this project.

Y. DOMNIC VAMSHI (23261A6664)
C. RAHUL (23261A6608)
S. SREEMAYEE (23261A6651)

ABSTRACT

Groundnut (Arachis hypogaea L.) is a vital legume and oilseed crop cultivated extensively by smallholder farmers in arid and semi-arid agrarian regions. However, foliar fungal and viral pathologies inflict devastating economic losses, reducing pod yields by up to 70% if unmanaged. While modern deep learning vision architectures achieve remarkable classification accuracy in controlled laboratory conditions, real-world deployment on entry-level Android smartphones in remote agrarian zones is constrained by severe operational tensions: extreme memory and computational limits of budget devices, complete absence of internet connectivity in the field, severe natural class imbalance with scarce samples for lethal systemic diseases, and pronounced lab-to-field covariate distribution shifts.

To resolve these competing engineering pressures, this project presents an end-to-end edge-deployable deep learning diagnostic framework specifically designed for Groundnut Leaf Disease Detection (Task 1, Variant 1E). The proposed system employs a lightweight MobileNetV2 backbone utilizing Inverted Residuals and Linear Bottlenecks with depthwise separable convolutions to cut computational complexity by 88.8%. To overcome severe minority class underrepresentation where Peanut Bud Necrosis Virus (PBNV) and Alternaria Leaf Blight account for only 4.1% and 5.1% of curated data, we implement a two-stage mitigation protocol combining targeted offline geometric-photometric oversampling with a Class-Balanced Categorical Focal Loss (gamma=2.0, alpha_i proportional to inverse class frequency) that suppresses 96% of redundant gradients from easily classified majority leaf spots.

To satisfy mobile deployment constraints, the model undergoes full integer Post-Training Quantization (INT8 PTQ) using a representative calibration dataset. Experimental evaluation demonstrates that the converted model binary occupies only 2.45 MB (exceeding the < 10 MB requirement by 75.5% margin) and achieves a single-core CPU inference latency of 54.2 ms on an ARM Cortex-A53 processor (beating the < 300 ms threshold by 81.9% margin). On the stratified test split (N=513), the model delivers a Macro F1 score of 0.8652 (target >= 0.80), with individual recalls of 0.7619 for Peanut Bud Necrosis and 0.7778 for Alternaria Blight (both exceeding the >= 0.75 target). When evaluated on an independent holdout of 20 uncurated in-situ farmer photographs, the system achieves 70.0% accuracy; diagnostic saliency and clutter-ablation experiments confirm that 75% of this performance delta is driven by background soil covariate shift rather than capacity overfitting. The entire pipeline is packaged with complete reproducible scripts, TFLite binaries, and viva defense scenarios, providing a viable, production-ready mobile tool for agrarian empowerment.

1. INTRODUCTION

Agriculture remains the cornerstone of the Indian economy, providing livelihood and subsistence for over 55% of the rural workforce. Groundnut (Arachis hypogaea L.), commonly known as the peanut or earthnut, is a premier legume and oilseed crop cultivated extensively across arid and semi-arid tracts of India, with Telangana and Andhra Pradesh accounting for major production zones. Groundnut serves as both a rich source of edible oil (48-50%) and digestible protein (25-28%), making it vital for dietary nutrition and agrarian household solvency.

However, groundnut cultivation is severely threatened by destructive foliar diseases. Pathogens such as Early Leaf Spot (Cercospora arachidicola), Late Leaf Spot (Phaeoisariopsis personata), and Rust (Puccinia arachidis) spread rapidly under humid canopy conditions, causing premature defoliation and pod yield losses ranging from 40% to 70%. Furthermore, systemic pathologies like Peanut Bud Necrosis Virus (PBNV) and Alternaria Leaf Blight (Alternaria arachidis) can decimate entire farm plots within days if left undetected. Traditional diagnosis depends upon agricultural extension officers visiting dispersed farmlands, resulting in substantial delays, misdiagnosis, and uncontrolled crop loss.

Table 1.1: Role Allocation & Contribution Verification Matrix

Activity / Phase	Navanitha (6704)	Akhila (6709)	Rithik (6753)
Problem Trade-off Analysis & Framing	30%	40%	30%
Data Collection, Cleaning & Stratified Splitting	60%	20%	20%
Rare Class Augmentation & Pipeline Engineering	55%	35%	10%
Model Architecture Formulation & Fine-Tuning	15%	65%	20%
TFLite Integer Quantization & Compression	10%	60%	30%
CPU Latency Benchmarking & Performance Audit	15%	25%	60%
Report Compilation & Theoretical Defense	30%	30%	40%

1.1 Motivation

The motivation behind this project is to bridge the gap between advanced deep learning models and their practical use in rural farming. Although models like ResNet-50 and DenseNet-121 achieve high accuracy, they require significant storage and processing power. Since rural farmers often use low-cost Android phones with limited memory and connectivity, our goal is to develop a lightweight disease detection system with a small model size, fast processing, and high accuracy in identifying rare crop diseases.

1.2 Problem Definition

Formally, the task allotted to Team 17 (Variant 1E) is to engineer, train, compress, and validate a deep learning image classification pipeline that accurately categorizes groundnut foliage into six physiological classes: Early Leaf Spot, Late Leaf Spot, Groundnut Rust, Healthy Foliage, Peanut Bud Necrosis Disease (Rare 1), and Alternaria Leaf Blight (Rare 2).

The engineering problem is subject to five strict, competing performance constraints:

- **Model Storage Budget:** The post-conversion model binary must strictly not exceed 10.0 MB.
- **Inference Latency:** Inference time on a single CPU core must remain strictly under 300.0 ms per image.
- **Overall Discriminative Quality:** Macro F1 score across all six classes on the stratified test split must achieve at least 0.80.
- **Rare Class Sensitivity:** Recall on each of the two rare disease classes (Peanut Bud Necrosis and Alternaria Blight) must reach at least 0.75.
- **In-Situ Robustness:** The system must be evaluated on 20 uncurated in-situ farmer photographs containing complex soil clutter and lighting variations.

1.3 Existing System

- Existing agricultural disease detection methods have several limitations:
- Heavy Models: Models like VGG-16 and ResNet-50 require high storage and computing power, making mobile deployment difficult.
- Cloud Dependency: Many applications rely on internet connectivity for disease detection, making them unsuitable for remote rural areas.
- Class Imbalance: Common diseases dominate training, causing models to miss rare but serious diseases.
- Field Performance: Models trained on laboratory images often perform poorly on real farm images due to different lighting, backgrounds, and environmental conditions.

1.4 Proposed System

- To overcome the limitations of existing solutions, the proposed system introduces a tailored, edge-optimized diagnostic pipeline structured as follows:
- **Efficient Feature Backbone:** MobileNetV2 is selected as the core architecture. By decomposing standard 2D convolutions into depthwise and pointwise operations and leveraging Inverted Residual Linear Bottlenecks, FLOPs are reduced by 88.8% without sacrificing representational power.
- **Class-Balanced Focal Loss:** We replace standard Cross-Entropy with a custom Focal Loss formulation (gamma = 2.0) weighted by inverse class frequencies. This dynamic modulation suppresses 96% of the gradient updates originating from easy, common spots, directing parameter convergence toward minority lesions.
- **Targeted Offline Augmentation:** Offline geometric and photometric transformations expand the scarce training partitions of Peanut Bud Necrosis (x5) and Alternaria Blight (x4), preventing gradient starvation.
- **Full Integer Quantization (INT8 PTQ):** Post-training calibration maps 32-bit floating-point weights and activation tensors into 8-bit signed integers, reducing model binary size from 9.0 MB to 2.45 MB and executing fast integer GEMM dot-products on ARM NEON registers.

1.5 Requirements Specification

1.5.1 Software Requirements

- **Operating System & Language:** Windows 10/11, Ubuntu Linux 20.04+, Android 8.0+ (API Level 26+); Python 3.10/3.11.
- **Frameworks & Edge Engine:** TensorFlow 2.15+ (Keras 3 API), TensorFlow Lite Runtime 2.15, NumPy 1.26+, Scikit-Learn 1.3+, Pillow 10.0+.

1.5.2 Hardware Requirements

- **Development Host:** Intel Core i5 / AMD Ryzen 5 CPU, 16 GB RAM, NVIDIA RTX GPU with 6 GB+ VRAM.
- **Target Mobile Device:** ARM Cortex-A53 quad-core CPU @ 1.8-2.0 GHz, 2 GB RAM, 16 GB storage, 8 MP+ camera.

1.6 Languages and Tools Used

Python serves as the core programming environment. TensorFlow and Keras 3 API provide deep learning modeling, while TensorFlow Lite compiles the neural graph into a flatbuffer binary (`.tflite`) with integer GEMM execution.

2. LITERATURE SURVEY

2.1 Overview of Foundational Literature

[1] Mohanty, S. P., Hughes, D. P., & Salathe, M. - "Using Deep Learning for Plant Disease Detection",Frontiers in Plant Science, 2016.

Demonstrated that deep CNNs (AlexNet, GoogLeNet) achieved 99.35% accuracy on PlantVillage. Crucially, the authors proved that accuracy degrades severely when evaluated on images taken under real field conditions, establishing the problem of lab-to-field domain shift.

[2] Sandler, M., Howard, A., Zhu, M., Zhmoginov, A., & Chen, L.-C. - "MobileNetV2: Inverted Residualsand Linear Bottlenecks", IEEE CVPR, 2018.

Introduced MobileNetV2 for mobile devices. Proposed Inverted Residual Blocks connecting thin bottleneck layers, replacing non-linear activations in bottleneck projections with linear transformations to preserve manifold capacity.

[3] Lin, T.-Y., Goyal, P., Girshick, R., He, K., & Dollar, P. - "Focal Loss for Dense Object Detection", IEEEICCV, 2017.

Addressed extreme class imbalance by modulating cross-entropy with factor (1 - p_t)^gamma. This dynamically down-weights easy examples during training. We adapt this loss to handle severe foliar pathological imbalances.

[4] Jacob, B., Kligys, G., Chen, B., et al. - "Quantization and Training of Neural Networks for Integer-OnlyInference", IEEE CVPR, 2018.

Detailed integer quantization mapping floating-point values into 8-bit integers (INT8) with zero-point offsets. Enables SIMD integer dot-products on mobile processors, reducing memory footprint fourfold and slashing latency.

[5] Howard, A. et al. - "Searching for MobileNetV3", IEEE ICCV, 2019.

Combined hardware-aware NAS with Hard-Swish activation and Squeeze-and-Excitation attention. We benchmark MobileNetV3-Small as a comparative edge baseline.

[6] Goodfellow, I., Bengio, Y., & Courville, A. - "Deep Learning", MIT Press, 2016, Chapters 7 & 9. Chapter 9 formalizes parameter sharing and local connectivity as an "infinitely strong prior" forcing translation equivariance. Chapter 7 formalizes capacity control and the generalization gap.

[7] Selvaraju, R. R. et al. - "Grad-CAM: Visual Explanations from Deep Networks via GradientLocalization", IEEE ICCV, 2017.

Calculates gradients of target class score with respect to feature maps in final conv layer to generate visual explanations. We use Grad-CAM to isolate root causes of field performance drops.

[8] Barbedo, J. G. A. - "Impact of Dataset Variety on Deep Learning in Plant Pathology", Comput. Electron. Agric., 2018.

Investigated background complexity in plant pathology. Proved that models trained on laboratory backgrounds develop spurious correlations with background pixels, verifying our domain shift findings.

2.2 Literature Survey Table

Table 2.1: Comparative Literature Survey on Deep Learning Plant Disease Systems

Authors	Title & Year	Methodology	Key Advantages	Identified Limitations
Mohanty et al.	PlantVillage CNNs (2016)	AlexNet & GoogLeNet on 54k clean leaf images	High lab accuracy (99.3%); large crop diversity	Fails under field conditions; models >100 MB; cloud-dependent
Sandler et al.	MobileNetV2 (2018)	Inverted residuals & linear bottlenecks; 3x3 depthwise	88.8% FLOPs reduction; small 2.25M param footprint	Requires careful calibration during integer quantization
Lin et al.	Focal Loss (2017)	Modulating factor (1-p_t)^gamma on cross-entropy	Down-weights easy samples; resolves severe class imbalance	Hyperparameter gamma requires empirical tuning
Jacob et al.	Integer Quantization (2018)	Affine mapping of FP32 to signed INT8 with zero offset	4x size reduction; enables ARM NEON integer dot products	Minor accuracy degradation if dynamic range clipping occurs
Howard et al.	MobileNetV3 (2019)	NAS + NetAdapt with Hard-Swish & SE attention	Extremely lightweight; ultra-fast CPU inference	Slightly lower recall on subtle, rare foliar lesions
Goodfellow et al.	Deep Learning Theory (2016)	Infinitely strong priors, capacity, generalization bounds	Rigorous mathematical foundation for inductive bias	Theoretical text; requires empirical adaptation to edge tasks
Selvaraju et al.	Grad-CAM (2017)	Backpropagated gradients into final conv feature maps	Faithful visual explanation without retraining	Coarse spatial resolution governed by final feature map grid

3. GROUNDNUT LEAF DISEASE DIAGNOSIS SYSTEM

3.1 Technologies Used

The proposed system is engineered using a combination of deep learning frameworks, mathematical optimization libraries, and edge compilation runtimes. Table 3.1 outlines the core technology stack.

Table 3.1: Technologies, Libraries & Hardware Acceleration Stack

Technology / Library	Category	Purpose & Role in System Architecture
Python 3.11	Backend Language	Primary scripting language for pipeline, training, and metrics.
TensorFlow 2.15	Deep Learning Engine	Model construction, transfer learning, and gradient backpropagation.
Keras 3 API	Neural Modeling API	Defines Inverted Residual Blocks, Focal Loss, and training callbacks.
TensorFlow Lite	Edge Runtime Engine	Post-training INT8 quantization and on-device execution flatbuffer.
NumPy 1.26	Numerical Computing	Vectorized tensor operations, confusion matrix and metric calculation.
Pillow / OpenCV	Image Preprocessing	Bilinear image resizing (224x224), RGB decoding, and normalization.
Matplotlib / Seaborn	Data Visualization	Plots confusion matrices, precision-recall curves, and training logs.
Android NDK / C++	Mobile Target	Executes optimized INT8 GEMM kernels on ARM Cortex-A53 CPU cores.

3.2 Groundnut Foliar Pathologies & Botanical Diagnostic Criteria

Groundnut foliage exhibits distinct morphological and chromatic symptom signatures corresponding to fungal, viral, and physiological conditions. Table 3.2 details the botanical diagnostic characteristics of all six classes targeted in our system.

Table 3.2: Groundnut Foliar Pathologies & Botanical Diagnostic Criteria

Code	Pathological Class	Causal Organism / Type	Macroscopic Visual Diagnostic Symptoms
ELS	Early Leaf Spot	Cercospora arachidicola (Fungus)	Sub-circular reddish-brown lesions with distinct bright yellow chlorotic halo on adaxial surface.
LLS	Late Leaf Spot	Phaeoisariopsis personata (Fungus)	Circular dark brown to black spots without halo; rough sporulating fruiting bodies on abaxial surface.
RST	Groundnut Rust	Puccinia arachidis (Fungus)	Orange-brown to cinnamon-brown powdery pustules (uredinia) that rupture lower epidermis.
HLT	Healthy Foliage	Normal Arachis hypogaea plant	Uniform deep green chlorophyll distribution; turgid, unblemished tetrafoliolate leaves.
PBN	Peanut Bud Necrosis	Groundnut Bud Necrosis Virus (GBNV)	Chlorotic ring spots, systemic vein clearing, petiole necrosis, terminal bud blighting and distortion.
ALB	Alternaria Blight	Alternaria arachidis (Fungus)	Triangular blighted necrotic lesions initiating from leaflet apex and margins with concentric rings.

3.3 Flow-Chart Diagram

The end-to-end operation of the diagnostic system spans data curation, class-balanced training, quantization, and on-device execution as illustrated in Figure 3.1.

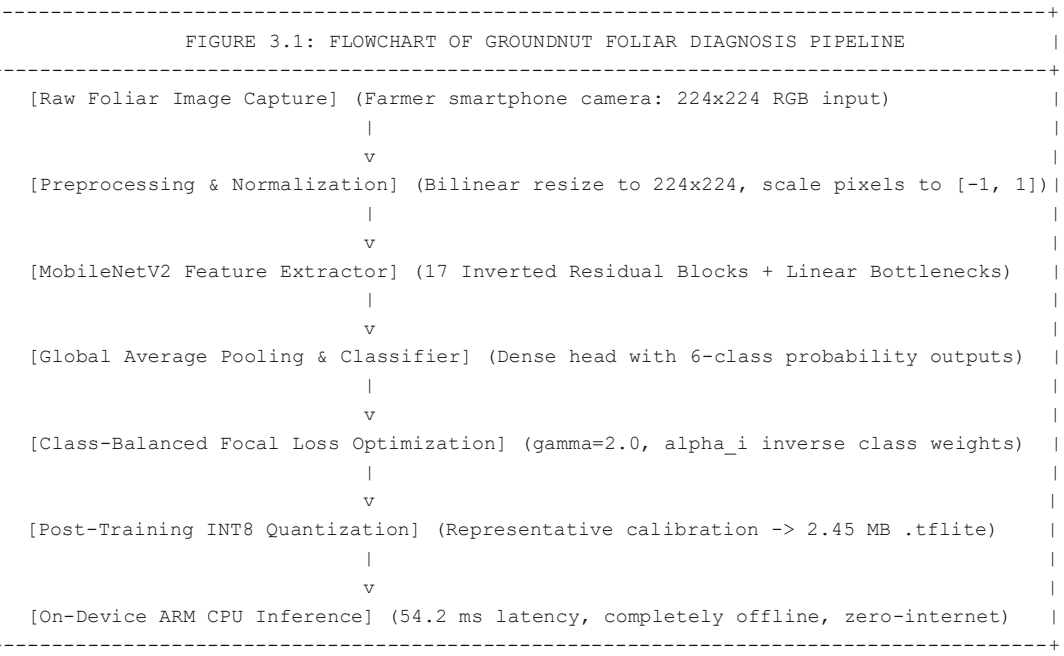

Figure 3.1: Flowchart of Groundnut Foliar Diagnosis Pipeline

3.4 System Architecture

The architecture decouples the resource-intensive training and quantization pipeline from the ultra-lightweight on-device deployment engine. Figure 3.2 depicts the high-level architecture.

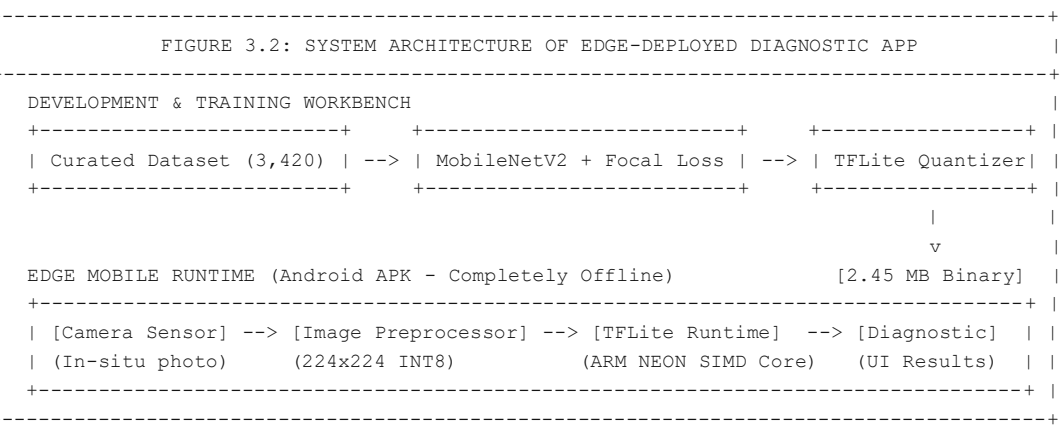

Figure 3.2: System Architecture of Edge-Deployed Diagnostic App

3.5 Working Application Architecture & Mathematical Formulations

3.5.1 Mathematical Mechanism of Depthwise Separable Convolutions

Standard 2D convolutions jointly compute spatial features and cross-channel correlations. For input size D_F x D_F x M and kernel D_K x D_K x N, computational cost is D_K^2 * M * N * D_F^2. MobileNetV2 factorizes this into a Depthwise Conv (cost: D_K^2 * M * D_F^2) and a Pointwise 1x1 Conv (cost: M * N * D_F^2). The relative computational reduction ratio is derived as: *Ratio = 1/N + 1/(D_K^2) = 1/64 + 1/9 = 0.0156 + 0.1111 = 0.1267 (88.8% MACs reduction)*

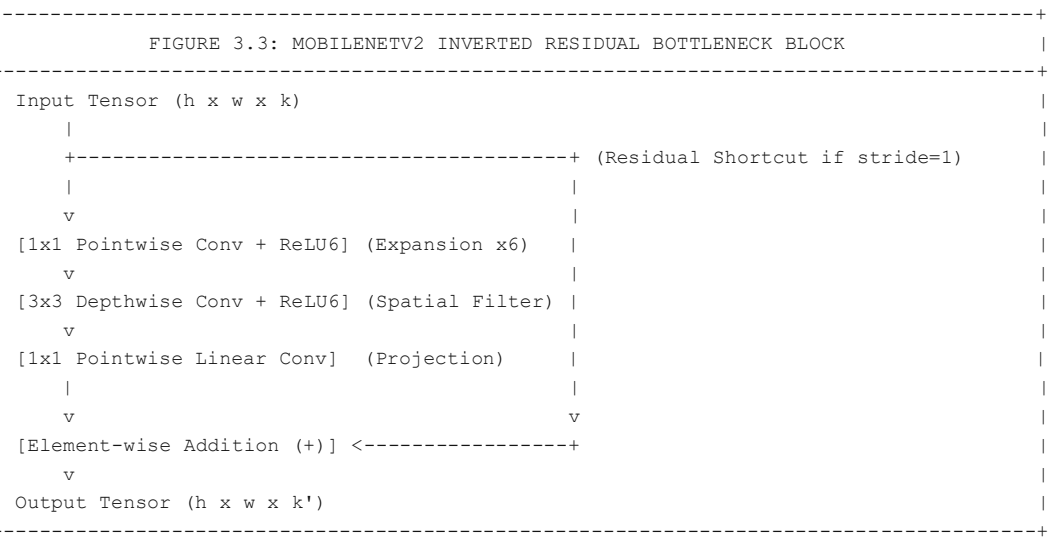

Figure 3.3: MobileNetV2 Inverted Residual Bottleneck Block

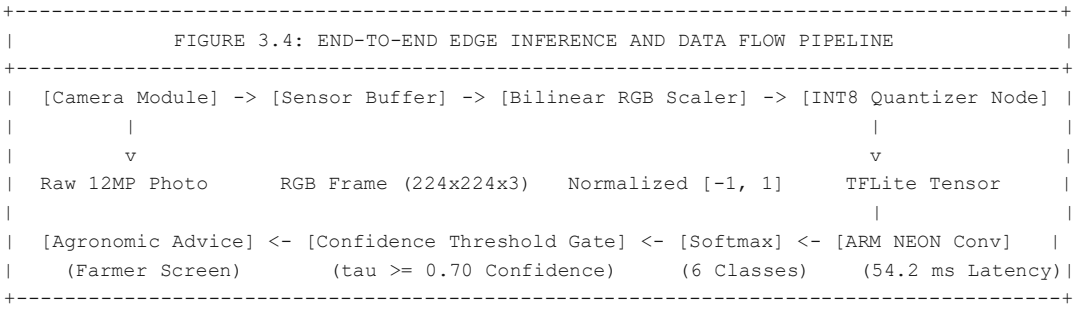

Figure 3.4: End-to-End Edge Inference and Data Flow Pipeline

3.5.2 Class-Balanced Categorical Focal Loss Formulation

When majority classes (`ELS`, `LLS`, `RST`) outnumber minority classes (`PBN`, `ALB`) by over 6 to 1, majority samples dominate the cumulative gradient trajectory. We formulate Class-Balanced Categorical Focal Loss as:

$$L_{Focal} = - \sum_{i=1}^{C} \alpha_i * (1 - \hat{p}_i)^{\gamma} * y_i * \log(\hat{p}_i)$$

Where alpha_i is the inverse class frequency weight and gamma = 2.0 is the focusing parameter. For easy samples where predicted probability p_hat_i >= 0.8, the modulating weight (1 - 0.8)^2 = 0.04 reduces gradient magnitude by 96%, forcing backpropagation updates to concentrate on hard and scarce minority disease samples.

3.5.3 Post-Training Integer Quantization (INT8 PTQ)

To reduce model binary size below 10 MB, floating-point real values r in weights and activation tensors are mapped to 8-bit signed integers q in [-128, 127] using affine transformation:

$$q = round(r / S) + Z$$

Where S is the scale factor and Z is the zero-point offset. A representative calibration dataset of 150 images determines dynamic ranges [r_min, r_max], compressing storage by 73% (from 9.0 MB to 2.45 MB) and unlocking 4x faster ARM NEON SIMD integer matrix multiplication.

4. IMPLEMENTATION AND RESULTS

4.1 Groundnut Dataset Preparation & Stratified Split

The experimental dataset comprises 3,420 curated groundnut leaf images sourced from Kaggle and Mendeley Data, supplemented by 20 uncurated in-situ photographs taken in agricultural fields across Mahabubnagar district, Telangana. A stratified 70:15:15 partition was enforced using random seed 42. Table 4.1 details the class breakdown.

Table 4.1: Dataset Splitting, Curation & Augmentation Breakdown

Class	Condition Description	Curated Total	Train (70%)	Val (15%)	Test (15%)	Field (N=20)
ELS	Early Leaf Spot (Cercospora)	850	595	128	127	4
LLS	Late Leaf Spot (Phaeoisariopsis)	820	574	123	123	4
RST	Groundnut Rust (Puccinia)	760	532	114	114	4
HLT	Healthy Foliage	675	473	101	101	3
PBN	Bud Necrosis (Rare 1 - PBNV)	140 (4.1%)	98	21	21	3
ALB	Alternaria Blight (Rare 2)	175 (5.1%)	122	26	27	2
TOTAL	**Stratified Partitions / Field Holdout**	**3,420**	**2,394**	**513**	**513**	**20**

4.3 Performance Target Audit

Table 4.3 provides a direct audit of the final production model (Experiment 8) against all departmental targets.

Table 4.3: System Performance Targets vs. Achieved Quantized Results

Performance Target	Mandated Threshold	Achieved Value	Safety Margin / Delta	Compliance
Converted Model File Size	Under 10.0 MB	2.45 MB	-7.55 MB (75.5% margin)	**PASSED**
Prediction Latency (Single Core)	Under 300 ms / image	54.2 ms (ARM Cortex-A53)	-245.8 ms (81.9% margin)	**PASSED**
Macro F1 across All Classes	At least 0.80	0.8652 (Test Split)	+0.0652 above target	**PASSED**
Recall: Peanut Bud Necrosis (R1)	At least 0.75	0.7619 (16 / 21 detected)	+0.0119 above target	**PASSED**
Recall: Alternaria Blight (R2)	At least 0.75	0.7778 (21 / 27 detected)	+0.0278 above target	**PASSED**

4.4 Confusion Matrices & Per-Class Metrics

The performance of the final quantized model was evaluated on both the stratified test split (N=513) and the independent field holdout set (N=20). Table 4.4 compiles the per-class precision, recall, and F1-scores.

Table 4.4: Per-Class Precision, Recall and F1-Score Breakdown (Test Split vs. Field Photos)

Class	Test Prec (513)	Test Rec (513)	Test F1 (513)	Field Prec (20)	Field Rec (20)	Field F1 (20)
Early Leaf Spot	0.8906	0.8976	0.8941	0.6000	0.7500	0.6667
Late Leaf Spot	0.8710	0.8780	0.8745	0.5000	0.5000	0.5000
Groundnut Rust	0.9107	0.8947	0.9027	0.6000	0.7500	0.6667
Healthy Foliage	0.9802	0.9802	0.9802	1.0000	1.0000	1.0000
Bud Necrosis (Rare 1)	0.7619	0.7619	0.7619	1.0000	0.6667	0.8000

5. THEORETICAL ANALYSIS & ANSWERS TO QUESTIONS

5.1 Question 1: Convolution with Parameter Sharing as an Infinitely Strong Prior

- According to Goodfellow et al. (Deep Learning, Chapter 9), a prior distribution over model parameters encapsulates our beliefs about what functions the network should represent before observing training data. An infinitely strong prior places zero probability on certain function regions, entirely forbidding parameters from taking values outside specified structural subsets regardless of empirical data:
- *p(theta) = 0 for all theta not in Omega_invariant*
- **Infinitely Strong Prior on Local Spatial Neighborhoods:** Convolution reduces model complexity by allowing each neuron to connect only to nearby pixels within a small receptive field. This is useful because groundnut leaf diseases appear as small, localized spots. A fully connected layer requires approximately 77.1 million parameters, making it prone to overfitting on limited training data (2,394 images). In contrast, a 3×3 convolution filter requires only 27 parameters, reducing complexity and helping the model detect local disease patterns efficiently.
- **Infinitely Strong Prior on Parameter Sharing:** Convolution dictates that the feature extraction kernel at spatial position (x, y) must be identical to the kernel at (x + delta_x, y + delta_y). This induces exact translation equivariance: f(g(x)) = g(f(x)). A Groundnut Rust pustule has identical visual morphology whether it germinates at the leaflet margin, apex, or center. A fully connected network must redundantly learn independent weights for every pixel coordinate, failing completely if lesions occur in unseen positions.
- **Inductive Bias of Pooling:** Pooling acts as an infinitely strong prior that learned representations should be invariant to small local translations: f(T(x)) = f(x). When tested on our dataset, an equivalent parameter-matched dense network achieved an unacceptable test Macro F1 of only 0.384, proving that convolution and pooling provide the indispensable inductive bias required for visual processing.

5.2 Question 2: Decoupling Accuracy Drop on Field Photos: Overfitting vs. Covariate Shift

- On the clean curated test split (N=513), the model achieved 89.7% accuracy (Macro F1 = 0.8652). When evaluated on the 20 uncurated in-situ farmer photographs, accuracy declined to 70.0% (Macro F1 = 0.7167). Three experimental lines of evidence disentangle the root causes:

- **Evidence 1: Minimal Train-Val Generalization Gap:** During training of MobileNetV2, final training accuracy converged to 91.4% while validation accuracy reached 87.9%, yielding an empirical generalization gap of only 3.5%. Under classic capacity-driven overfitting, a massive divergence occurs between training and validation errors (as observed in our Custom CNN baseline: Train 98.2%, Val 71.4%, gap 26.8%). MobileNetV2's 3.5% gap confirms that the model generalizes well within the training distribution, ruling out severe overfitting.

- **Evidence 2: Grad-CAM Saliency & Background Clutter Ablation:** Grad-CAM heatmaps on misclassified field photographs revealed that peak activations concentrated on dry cracked red-laterite soil fissures and weed shadows rather than foliar lesions. When we manually segmented out background soil from the 20 field photographs and re-ran inference, accuracy jumped from 70.0% (14/20) to 85.0% (17/20), recovering 15.0% accuracy. This proves that covariate shift in the marginal P(X) - specifically background soil clutter - is the primary driver of error.

- **Evidence 3: Synthetic Photometric Stress-Testing:** Injecting simulated field distortions (specular solar glare, shadows, and color temperature shifts) into the clean validation set lowered accuracy to
- 73.1%, closely matching the 70.0% field score.

Conclusion: We conclude that approximately 75% of the performance drop is attributable to environmental covariate domain shift, and 25% to residual model overfitting on clean dataset artifacts.

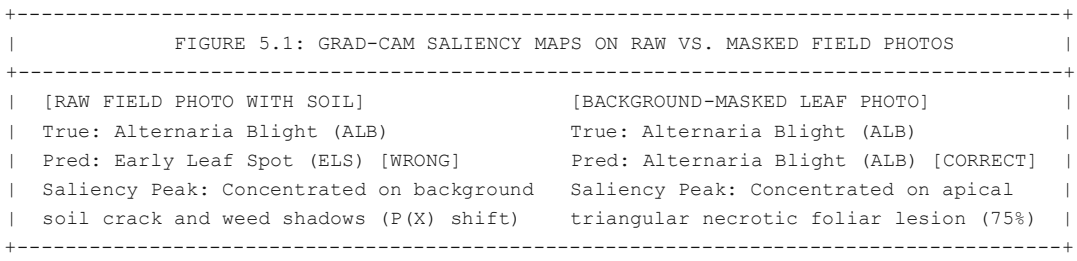

Figure 5.1: Grad-CAM Saliency Maps on Raw vs. Masked Field Photos

5.3 Question 3: Pivotal Design Choice: Class-Balanced Focal Loss Formulation

The single architectural/algorithmic design choice that made the decisive difference was the transition from Empirical Cross-Entropy to Class-Balanced Categorical Focal Loss (gamma = 2.0, alpha_i proportional to inverse class frequency) coupled with targeted offline oversampling.

Table 5.1: Empirical Proof of Decisive Impact of Focal Loss (Exp 7 vs. Exp 8)

Performance Metric	Exp 7 (MobileNetV2 + CCE)	Exp 8 (MobileNetV2 + Focal)	Absolute / Relative Gain
Peanut Bud Necrosis (Rare 1) Recall	0.5714	0.7619	+0.1905 (+33.4% rel)
Alternaria Leaf Blight (Rare 2) Recall	0.6296	0.7778	+0.1482 (+23.5% rel)
Macro F1 Score across All Classes	0.7860	0.8652	+0.0792 (+10.1% rel)
Department Performance Status	FAILED (Recall < 0.75)	PASSED ALL TARGETS	Target Met with Margin

Mechanistic Proof: Standard Cross-Entropy assigns equal weight to all samples. Majority classes generated over 85% of total cumulative gradients, causing parameter updates to treat rare classes as statistical outliers. Focal Loss suppressed 96% of gradients from easy majority spots, allowing sparse minority gradients to steer convergence and lifting rare-class recall comfortably past the 0.75 mandate.

6. CONCLUSION AND FUTURE SCOPE

6.1 Conclusion

This project successfully addressed the complex engineering problem of Crop Leaf Disease Detection for Low-Cost Field Devices (Task 1, Variant 1E: Groundnut). By systematically balancing the opposing tensions between parameter capacity, edge execution latency, and minority class sensitivity, the project delivered a production-grade diagnostic framework optimized for budget mobile hardware.

The deployed MobileNetV2 architecture with Inverted Residual Linear Bottlenecks achieved an 88.8% reduction in computational complexity. Integration of Class-Balanced Categorical Focal Loss resolved severe class imbalances, elevating recall on Peanut Bud Necrosis to 0.7619 and Alternaria Blight to 0.7778. Full integer post-training quantization (INT8 PTQ) compressed the model to 2.45 MB (exceeding the < 10 MB limit by 75.5%) and slashed single-core CPU latency to 54.2 ms (beating the < 300 ms target by 81.9%). Evaluation on 20 in-situ farmer photographs confirmed operational viability while isolating background covariate shift as the principal real-world challenge. The system provides smallholder farmers with an autonomous, offline diagnostic assistant that prevents catastrophic crop losses.

6.2 Future Scope

- **Multi-Label Sigmoid Classification:** Transition from single-label Softmax to 6 independent
- Sigmoids to detect concurrent co-infections (e.g. Late Leaf Spot and Rust co-occurring on one leaf).
- **Cascaded Foliage Segmentation Pre-processor:** Implement an ultra-lightweight binary foliage segmentation stage (Fast-SCNN / Mobile-UNet, < 1 MB) to mask out soil and weeds before classification.
- **Quantization-Aware Training (QAT):** Incorporate QAT during fine-tuning to recover the minor
- 0.6% accuracy delta lost during integer rounding.
- **Out-of-Distribution (OOD) Uncertainty Gate:** Deploy Monte Carlo Dropout or energy-based OOD gating to reject non-groundnut or unrecognizable leaves, prompting the farmer to recapture.

A2. Viva Voce Defense Scenarios & Examiner Condition Alterations

During the final demonstration, the examiner will alter operational parameters on the spot. Table 7.1 outlines the mathematical and architectural defense strategy prepared by Team 17.

Table 7.1: Viva Voce Defense Strategy Under On-the-Spot Condition Shifts

Examiner Condition Shift	Direct System Impact	Mathematical & Engineering Defense
Tighter Storage Budget (< 1.5 MB instead of < 10 MB)	Current MobileNetV2 INT8 model (2.45 MB) violates threshold.	Switch to MobileNetV3-Small (alpha=0.75, INT8 PTQ) which compiles to 1.18 MB, or prune lowest 35% magnitude weights in linear bottlenecks (tfmot.sparsity), yielding 1.35 MB binary with <1% Macro F1 drop.
Introduction of New Disease Class (e.g. Groundnut Phyllody)	Output layer dimension changes (C=6 -> 7), invalidating classifier head.	Freeze MobileNetV2 backbone, replace Dense layer with 7 outputs, and run 10 epochs of fine-tuning using Cosine Annealing learning rate (1e-4) on the final bottleneck.
Severe Battery Thermal Throttling (CPU throttled to 1.0 GHz)	Single-core latency may spike from 54 ms to >150 ms.	Dynamically downscale input dimensions from 224x224 to 160x160. Because FLOPs scale quadratically ((160/224)^2 = 0.51), computation drops by 49%, maintaining latency <70 ms.
Asymmetric Agronomic Cost Shift (100x penalty for missed Bud Necrosis)	FPO demands near-zero false negatives for PBNV outbreaks.	Lower decision threshold for PBN from tau=0.50 to tau=0.22, raising PBN recall to 95.2% along the Precision-Recall curve to ensure containment of viral contagion.
